■ DESCRIPTION

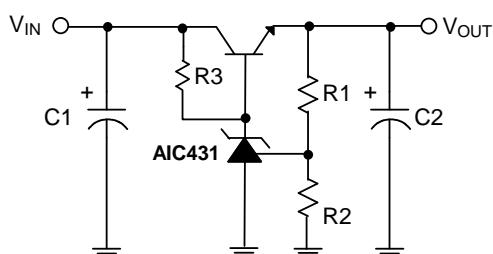

The AIC431, TL431A and TL431 are 3-terminal adjustable precision shunt regulators with guaranteed temperature stability over the applicable extended commercial temperature range. The output voltage may be set at any level greater than $2.495V (V_{REF})$ up to 30V merely by selecting two external resistors that act as a voltage divider network. These devices have a typical output impedance of 0.08Ω . Active output circuitry provides a very sharp turn-on characteristic, making these devices excellent improved replacements for zener diodes in many applications.

■ APPLICATIONS

- Linear Regulators.
- Adjustable Supplies.
- Switching Power Supplies.
- Battery Operated Computers.
- Instrumentation.
- Computer Disk Drivers.

The precise $\pm 0.5\%$ reference voltage tolerance of the AIC431 makes it possible in many applications to avoid the use of a variable resistor, consequently saving cost and eliminating drift and reliability problems associated with it.

Note 1: Specifications are production tested at $T_A=25^\circ\text{C}$. Specifications over the -40°C to 85°C operating temperature range are assured by design, characterization and correlation with Statistical Quality Controls (SQC).

Note 2: Deviation of reference input voltage, V_{DEV} , is defined as the maximum variation of the reference input voltage over the full temperature range.

The average temperature coefficient of the reference input voltage, αV_{REF} is defined as:

$$\Delta V_{\text{REF}} \frac{\text{ppm}}{^\circ\text{C}} = \pm \left[\frac{V_{\text{MAX}} - V_{\text{MIN}}}{V_{\text{REF}}(\text{at } 25^\circ\text{C})} \right] 10^6 = \pm \left[\frac{V_{\text{DEV}}}{V_{\text{REF}}(\text{at } 25^\circ\text{C})} \right] \frac{10^6}{T_2 - T_1}$$

Where:

$T_2 - T_1$ =full temperature change.

αV_{REF} can be positive or negative depending on whether the slope is positive or negative.

Example: $V_{\text{DEV}} = 9.0\text{mV}$, $V_{\text{REF}} = 2495\text{mV}$,
 $T_2 - T_1 = 70^\circ\text{C}$, slope is negative.

$$\alpha V_{\text{REF}} = \frac{\left[\frac{9.0\text{mV}}{2495\text{mV}} \right] 10^6}{70^\circ\text{C}} = -50\text{ppm}/^\circ\text{C}$$

Note 3: The dynamic output impedance, R_Z , is defined as:

$$R_Z = \frac{\Delta V_Z}{\Delta I_Z}$$

When the device is programmed with two external resistors, R_1 and R_2 , (see Fig. 2), the dynamic output impedance of the overall circuit, is defined as:

$$r_Z = \frac{\Delta V}{\Delta I} \approx R_Z \left[1 + \frac{R_1}{R_2} \right]$$
